Comment on "Triplet-to-Singlet Exciton Formation in poly(p-phenylene-vinylene) Light-Emitting Diodes"

Lin *et al.* claim to have determined the ratio γ of triplet to singlet excitons in poly(p-phenylene-vinylene) (PPV) light emitting diodes by measuring the singlet and triplet absorption spectra under conditions of optical and electrical excitation[1]. The authors find that (a) $\gamma >> 3$ at weak electric fields, and (b) $\gamma < 3$ at moderate electric fields. This steep electric field dependence and $\gamma < 3$ at moderate fields is explained assuming : (i) initial formation of a high energy triplet T_2 from the triplet electron-hole (e-h) pair, which lies slightly below the e-h continuum and which is dipole allowed from the lowest triplet T_1, (ii) a phonon bottleneck[2] in the nonradiative relaxation from T_2 to T_1, due to the large energy gap between them, and (iii) the competing field-induced dissociation of the T_2 exciton, and the consequent suppression of γ. The authors quote reference 3 to state that since the higher energy singlet exciton S_2 is only 0.3 eV above S_1, phonon bottleneck and field induced dissociation are absent in the singlet channel.

The lowest excitations in PPV can be simulated within the Pariser-Parr-Pople model for linear polyenes with artificially large effective bond alternation[4],

$$H = -\sum_{i,\sigma} t(1 \pm \delta)(c^{\dagger}_{i\sigma} c_{i+1,\sigma} + h.c.) + U\sum_i n_{i\uparrow} n_{i\downarrow} + \sum_{i<j} V_{ij}(n_i - 1)(n_j - 1) \qquad (1)$$

where all terms have their usual meanings. Using the standard U and t, Ohno parametrization for V_{ij} and $\delta = 0.2$[4] we have calculated the exact singlet and triplet energies for the chain with N = 12 atoms. In Fig. 1, we show the exact triplet energy spectrum between T_1, hereafter $1^3B_u^-$, and the dipole-coupled T_2, hereafter $1^3A_g^+$. We have also included the optical singlet exciton S_1 ($1^1B_u^-$) and the singlet exciton $m^1A_g^+$, which has the largest transition dipole with the $1^1B_u^-$ within (1) (the quantum number m is N-dependent and is 8 in N = 12)[5], and is closer to the e-h continuum[6] than the $1^3A_g^+$. The $m^1A_g^+$ is observable in nonlinear spectroscopy[5,7] which places this state above the S_2 state calculated in reference 3 and cited by Lin *et al.* The S_2 state in reference 3 is the lowest two-photon state $2^1A_g^+$ of PPV and not the $m^1A_g^+$. The energy gap between the $m^1A_g^+$ and the $1^1B_u^-$ is at least as dense as that between the $1^3A_g^+$ and the $1^3B_u^-$, and hence there exist singlet excitons nearly degenerate with $1^3B_u^-$. The large energy of the $1^1B_u^-$ and the large energy gaps in Fig. 1 are finite size effects. With increasing N, absolute energies as well as energy differences decrease rapidly[5] and additional levels appear in the energy gaps. Different theoretical treatments have confirmed this picture of the long chain limit[8,9].

Two conclusions emerge from Fig. 1. First, the triplet

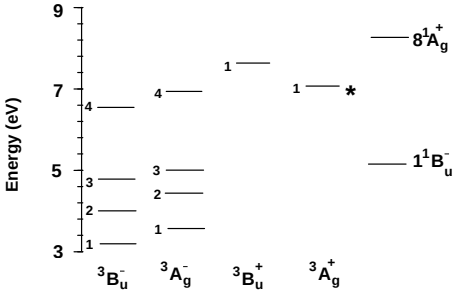

FIG. 1: The triplet energy spectrum between the $1^3B_u^-$ and the $1^3A_g^+$ in a N = 12 chain relative to the singlet ground state. Different symmetry subspaces are shown separately. State marked by asterisk is dipole-coupled to the $1^3B_u^-$. The $1^1B_u^-$ and the $m^1A_g^+$ ($m = 8$ in N = 12) are also included.

spectrum between T_1 and the lowest dipole connected triplet, the so called T_2 in reference 2 is very dense in long chains. Absorption measurements miss all the dipole–forbidden states in between. Hence the phonon bottleneck in the nonradiative relaxation[1,2] will not occur. The observed field dependence[1] of γ therefore cannot be explained within Lin et al.'s model. Second, the formation of the $1^3B_u^-$ triplet exciton via the $m^3A_g^+$ would imply similar formation of the $1^1B_u^-$ singlet exciton via the $m^1A_g^+$. If indeed the energy spectra *were* sparse, contradicting our calculations, then exciton dissociation would be larger in the singlet channel due to the closer proximity of the $m^1A_g^+$ to the e-h continuum. This would have caused a field dependence of γ opposite to what is observed by the Lin *et al.*[1]. Our theoretical results therefore cast severe doubts on Lin *et al.'s* model, and by implication on the experimental results themselves.
